Main conclusions

Wave spectra on a subscene-by-subscene basis are poorly constrained.

- Cut-off limits the directional sensitivity.
- Continuity should be exploited (Fireworks/models/statistical/group analysis).
- Wind-wave system should be better constrained (models/feature analysis).
- RAR can be improved (multi-sensor observations/multi-line-of-sight Harmony).
- Multi-scale neural-network approaches show potential.

Stress-equivalent wind, wave-Doppler, currents and long-ocean waves should be integrally estimated.

- All observations originate from the same surface.
- NRCS, Doppler, SAR spectra should be combined in one assimilation (neural networks).
- Neural networks for full spectra, not only integral parameters.
- · Causal filtering in iterative approaches or external wind and waves models.

Closed-form mapping: misregistration in space, phase changes in Fourier domain

- Spectral mapping (Hasselmann & Hasselmann, 1991; Krogstad et al. 1992/1994).
- The misregistration is associated to both range and azimuth random shifts.
- Azimuth shifts are directly associated to detected scatter velocities: it can be polarization and wavelength dependent.
- Shifts scale with the R/V parameter.
- Under joint-Gaussian statistical assumption (and stationary conditions), a spectral closed form can be derived:

$$P(k_x, k_y) = \frac{1}{(2\pi)^2} \int \int G(x, y, k_x, k_y) e^{-i(k_x x + k_y y)} dx dy$$

$$P(k_x,k_y) = \frac{1}{(2\pi)^2} e^{-k_x^2 \rho_{xx}(0,0) - k_y^2 \rho_{yy}(0,0) - k_x k_y(\rho_{xy}(0,0) + \rho_{yx}(0,0))} \int \int e^{k_x^2 \rho_{xx} + k_y^2 \rho_{yy} + k_x k_y(\rho_{xy} + \rho_{yx})} L e^{-i(k_x x + k_y y)} dx dy,$$

IMACS

- Systematic and massive computation of x-spectra @17.7 km from Sentinel-1 IW SLC products allowed for statistical analysis of IMACS to refine Li et al. (JGR 2019) analysis.
- About 180,000 x-spectra have been colocated with ECMWF and WW3 model outputs
- In the contrary of VV, the IMACS sensitivity to geophysical parameters is found negligible in VH on the dataset used for this study.
- A Strong dependence is found with respect to wind speed and direction.
- An Asymmetry is obtained between Upwind and Downwind absolute values. Upwind>downwind. Second order effect.
- The incidence angle dependence is also found to be a second order effect.

Cut-off estimation

- Estimated by fitting a Gaussian to the ACF (Vachon et al. 1993; Kerbaol et al. 1998).
- Proportional to the velocity variance.
- Required to constrain the wind-wave spectrum, e.g. the wave-age parameter.
- Removal of the non-linear part in the Sentinel-1 OSW spectra (Sentinel-1 ATBD).

📱 💶 📕 📕 🧮 🚍 🛶 🚺 🛌 📕 💥 🔚 🖬 📰 💷 💷 🕍 🔸 The European space Agency

eesa

Cut-off fitting issues

- Limited surface roughness at low wind speeds.
- Overestimation because scene is not properly resolved.
- Underestimation with swell in the range direction.

- Resolved waves affect the cut-off estimation.
- Waves in the azimuth direction can introduce sinc-like behavior.
- Steep waves across track cause underestimation.
- Lower waves across track cause underestimation.
- Only empirical corrections (Stopa et al. 2015).
- Possible mitigation: to use the second derivative of the first lags of the autocorrelation function in azimuth.

Figure from Stopa et al. (2019)

15

Quasi-linear inversion assessment using buoy data

eesa

- Quasi-linear inversion schemes.
- Rather well known and providing reasonable results, regardless of the intrinsic limitations.
- Focus in the analysis of SAR images acquired during varying wind and wave conditions: eg. under the presence of an atmospheric frontal system. Not so satisfactory results. (Lai and Delisi 2010)
- Next attempt, making use of the quasi-linear inversion scheme proposed originally by Krogstad et al. (1994) and used by Vachon et al (1994) –work under progress-
- Focus at detailed directional wave spectra
- Mixed sea and swell and studying the relative

Spectral coverage

- Limited directional sensitivity due to Azimuth cut-off.
- Cut-off typically 100-200 m.

 $\lambda_c \propto \pi \sqrt{\rho_{yy}(0,0)} = \pi \frac{R}{V} \sqrt{\sigma_v^2}$

- Wind-wave system requires parametrizations.
- Swell full recovered in low to moderate sea states.
- Issues with peak swell direction.

Figure from Hasselmann et al. (2012)

20

eesa

Known issues of the closed-form

- Limited spectral coverage.
- Time-varying geometry.
- Cut-off is affected by tilt, hydrodynamics and decorrelation.
- Cut-off estimation issues.
- Supercritical wave velocities and slopes.
- RAR response is poorly understood.

sa

Sentinel-1 archive inconsistency

- The ESA level-2 ocean swell spectra (OSW) product is improving over time through several IPF updates.
- The improvements are not currently applied backward in time.
- This work examines the temporal consistency of the OSW product as compared to a global wave model (Smith et al., 2020 RMetS GDJ).
- The match-up criteria is within 100 km and 30 mins.
- Comparisons are done over bulk params with wave model spectra truncated using azimuth cutoff (model S1 biases and std dev.).

Known issues on RAR modulations

 RAR modulation damping in wind following waves.

Supercritical velocities and slopes

(b)

(d)

shallow pool

deep pool

light source

sea surface elevation

pattern at bottom

radar power from target

(a) picture by Gregory Massal

- Most prominent at low wind-sea and monochromatic swell.
- Supercritical velocities (along-track monochromatic): $k_y A > \frac{V}{\omega B}$
- Supercritical slopes (common in altimetry):

 $k_x A > \tan(\theta)$

• Fully non-linear when $d > \lambda/4$ (Toshida et al. 2015).

Time-varying geometry and modulation

→ THE EUROPEAN SPACE AGENCY

- Observation geometry changes during acquisition time creates significant variation of backscattered signal.
- This cross-section variation is wrongly interpreted as wave motion in cross-spectrum.
- Wave direction of propagation can be inverted for sufficiently long wave (with negative azimuth wavenumber).

Mean impact on cross spectral phase

k [rad/m]

Mean phase spectra for \pm azimuth (upper) and \pm range (lower) winds. Left: wv1, Right: wv2. Ocean data.

eesa

Neural-network approaches

- Decomposition of spectrum (CWAVE, Schulz-Stellenfleth et al. 2005/2007).
- Estimation of integral wave parameters using (step-wise) regression.

- 'Engineered' machine learning for Sentinel-1 (Stopa & Mouche, 2017; Wang et al. 2018).
- Deep-learning approaches involving the full spectrum (Quach et al. 2021).

Deep-learning for sea-state retrieval

- <u>Wind-sea</u> related to present/recent winds: complex non-linearities and partially or totally removed from the SAR spectral signature (azimuthal cut-off).
- DNN method to estimate the windsea Hs from S1 with a data driven approach applied to either 2 estimations of the wind sea Hs variable:
 - o WW3 wind sea partition,
 - wind sea component of the wave spectrum (based on Cg and wind vector)
- <u>Dependence</u> to input features can be estimated overall and for various conditions:Skewness, Azimuth cutoff, various IMACS of longer wavelength for higher wind speeds.

LSTM to transform image spectra to wave spectra

- Sentinel-1 IW image spectra in the wind-wave dominant Baltic Sea; WAM based NORA3 wave spectra.
- 60k collocations; Vanilla LSTM recurrent neural network (~20k trainable parameters).
- Training objective is to minimize RMSE and maximize correlation.
- Validation on 7749 data points/spectra.
- Majority of spectra to spectra correlations are above 0.9.
- Correlations by frequency bins accurate; RMSE low for higher frequencies.
- For $H_{\rm S}$ calculated from spectra r = 0.91 and RMSE 0.3 m. For $T_{\rm m01} r = 0.84$ and RMSE 0.5 s.

SeaStaR (SAR Sea State Retrieval) empirical algorithm

Algorithm opportunities and implementation: SeaStaR (SAR Sea State Retrieval) new empirical algorithm

- Processing parameters output in form of fields (raster, e.g. one S1-IW with 3 km raster ca. 5000 values/image-ID)
- Series of integrated sea state parameters (8 parameters: SWH, Swell SW1, SW2, Windsea; Periods Tm0, Tm1, Tm2, Windsea-Period)
- Algorithm realized in Sea State Processor for daily Near Real Time (NRT) services (uniform modular architecture for different satellites)

Algorithm innovation

- Combination of classical approach using linear regression with machine learning (CWAVE approach + support vector machine SVM)
- Five types of SAR features: NRCS statistics, geophysical (wind), GLCM, spectral parameters + new introduced features, CWAVE
- Method applied for processing Level-1 (L1) products for different satellites (modes):
 - Sentinel-1 Wave Mode (S1-WV), SLC
 - Sentinel-1 Interferometric Wide Swath Mode (S1-IW), GRD
 - Sentinel-1 Extra Wide (S1-EW), GRD
 - TerraSAR-X StripMap (TS-X SM), GRD

Algorithm tasks

- Artefact (ships, fronts, etc.), SAR processing errors and antenna beam pattern filtering, denoising
- Features extraction, feature error analysis
- Model functions
- Control results, filtering, flagging
- Map Client

Achieved RMSE total significant wave height SWH (m) worldwide:

Limitations of neural-network approaches

- Current neural-network approaches only retrieve integrated parameters.
- Filters applied to capture various scales are not causal.
- Not all parameters from side-looking SARs are fully exploited.
- Input parameters such as the cut-off suffer from estimation issues.
- Neural networks still suffer from the single line-of-sight of Sentinel-1.
- If available \rightarrow multi-sensor constraints.
- Exploit improved ocean-wave models.

Sentinel-2-derived wave spectra

- Multispectral images are collected one at a time.
- Time difference can be exploited to estimate the phase velocity.
- Cross-spectrum between B04 and B08 channels pick out "true" direction of wave components for descending (respectively ascending) satellite acquisitions.

eesa

SAR altimetry spectra

- By normalization and reprojection on the ground it is possible to compute SAR spectra.
- Dominant mechanisms are velocity and range bunching.
- Only possible to retrieve swell in low to moderate sea states (SWH < 6 m).
- 'Cut-off' estimation (velocity variance) and swell retrieval might become essential to constrain the sea-state bias.

SAR altimetry spectra

SAR altimetry cross-spectral analysis

→ THE EUROPEAN SPACE AGENCY

- Zero-Doppler nadir-altimetry spectra have four ambiguities (both sides of track).
- Long overpass time O(2 s) allows for multiple sublooks and the generation of a cross-spectral stack.
- Modulations depend on geometry \rightarrow rotation of cut-off, change of phase and sensitivity changes.

Multi-scale Integrated Retrieval for Oceans (MIRO)

- High-resolution retrievals require multi-scale approaches and scene classification.
- NRCS, Doppler and SAR spectra originate from the same surface.
- NRCS, Doppler and SAR are originate from different wavelengths (and relaxation scales).
- Extend the deep-learning approaches.
- Adjoint wave modelling.
- Causal (iterative) filtering approaches.

→ THE EUROPEAN SPACE AGENCY

Toward an integrated approach for sea state retrieva

New opportunities and strategies for sea state parameter retrieval from RAW and complex (SLC) SAR acquisitions :

• Combination into a joint algorithm of Doppler, NRCS and xspectra (MACS, CWAVE,...) quantities to retrieve wind/waves/current.

- · Exploitation of wide-swath capabilities :
 - Take benefit of the expected spatial and temporal coherence of wind and waves fields on large scale.
 - Exploitation of the variability of the imaging mechanisms within the swath.
- Texture analysis (classification, wind properties, stability parameter, ...).
- Sea state-driven SAR compression (L0 -> L1).

Approved and proposed missions

- Bistatic SAR systems (Harmony)
- High-resolution multibeam SAR ATI (SEASTAR).
- Swath altimeters (Sentinel-3 Next Generation).
- Distributed systems (SWARMSAR).
- Dual-frequency altimeters (CRISTAL).
- L-band SAR systems (ROSE-L).
- Dual-frequency SAR systems (NISAR).
- Pencil-beam Doppler scatterometry.

Harmony

→ THE EUROPEAN SPACE AGENCY

- Three lines-of-sight.
- Range and Doppler not perpendicular.
- Rotated sensitivity.
- Enhanced spectral coverage.

$$T_y = -\frac{R_t \omega}{2U_t} (\frac{k_x}{|k|} 2\sin\theta_t + i2\cos\theta_t) = -\frac{R_t \omega}{U_t} (\frac{k_x}{|k|}\sin\theta_t + i\cos\theta_t)$$

$$\begin{split} T_x &= \frac{-\omega(\frac{k_x}{|k|}(\sin\theta_t + \sin\theta_r\cos\alpha) - \frac{k_y}{|k|}\sin\theta_r\sin\alpha + i(\cos\theta_t + \cos\theta_r))}{(\boldsymbol{U}_t \cdot \frac{\delta\hat{r}_t}{\delta x} + \boldsymbol{U}_r \cdot \frac{\delta\hat{r}_r}{\delta x}) + (\boldsymbol{U}_t \cdot \frac{\delta\hat{r}_t}{\delta y} + \boldsymbol{U}_r \cdot \frac{\delta\hat{r}_r}{\delta y})\frac{\delta y}{\delta x}} \\ T_y &= \frac{-\omega(\frac{k_x}{|k|}(\sin\theta_t + \sin\theta_r\cos\alpha) - \frac{k_y}{|k|}\sin\theta_r\sin\alpha + i(\cos\theta_t + \cos\theta_r))}{(\boldsymbol{U}_t \cdot \frac{\delta\hat{r}_t}{\delta x} + \boldsymbol{U}_r \cdot \frac{\delta\hat{r}_r}{\delta x})\frac{\delta x}{\delta y} + (\boldsymbol{U}_t \cdot \frac{\delta\hat{r}_t}{\delta y} + \boldsymbol{U}_r \cdot \frac{\delta\hat{r}_r}{\delta y})} \end{split}$$

Harmony-A Sentinel-1 Harmony-A Harmo

- Directional (i)MACS, cut-off and RAR.
- Polarimetric (i)MACS, cut-off and RAR.
- Additional constraints on the wind-wave system.

SEASTAR

- Better line-of-sight diversity than Harmony.
- Lower range resolution.
- Quad-pol transmission?

$$T_y = -\frac{R_t \omega}{2U_t} \left(\frac{k_x}{|k|} 2\sin\theta_t + i2\cos\theta_t\right) = -\frac{R_t \omega}{U_t} \left(\frac{k_x}{|k|}\sin\theta_t + i\cos\theta_t\right)$$

$$T_x = \frac{-\omega(\frac{k_x}{|k|}\sin\theta\cos\alpha - \frac{k_y}{|k|}\sin\theta\sin\alpha + i\cos\theta)}{(\boldsymbol{U}\cdot\frac{\delta\hat{r}}{\delta x}) + (\boldsymbol{U}\cdot\frac{\delta\hat{r}}{\delta y})\frac{\delta y}{\delta x}}$$
$$T_y = \frac{-\omega(\frac{k_x}{|k|}\sin\theta\cos\alpha - \frac{k_y}{|k|}\sin\theta\sin\alpha + i\cos\theta)}{(\boldsymbol{U}\cdot\frac{\delta\hat{r}}{\delta x})\frac{\delta x}{\delta y} + (\boldsymbol{U}\cdot\frac{\delta\hat{r}}{\delta y})}$$

Sentinel-3 Next Generation Topography

esa

- Near-nadir incident angles.
- Velocity and range bunching dominant.
- Closed-form only applicable in low sea states.
 - Non-linear range bunching.
 - Supercritical waves.

SWARMSAR

- SwarmSAR is a MIMO like configuration
- All nodes illuminate the same area of interest
- Each node has a basic imaging capabilities
- Resolution capabilities increase when nodes work together.

Parameters	Value	
Satellites height	693 km	
Satellite Separation	100 m	
Satellites velocity	7000 km/h	
Operating frequency	2.9 GHz (S-band)	
Wind speed	10 m/s	
Correlation Time	30 ms	
No. of Sensors	5

Summary and conclusions

- SAR retrieval algorithms:
 - Limited improvements in closed-form retrievals (~2003-2020).
 - Emergence of (parametrized) neural-network approaches (~2005-2020).
- Current work (~2020-2023):
 - Improvements in the closed-form model and inversion.
 - Exploitation of continuity in wave fields (Fireworks).
 - Deep-learning retrievals.
 - Assimilation of wave data into models.
 - Multi-sensor approaches.
 - Satellite radar altimetry as a new source for wave-spectrum estimation.
 - Retrieval algorithms for proposed and approved missions.
 - SARWAVE: <u>https://www.sarwave.org/</u>

Recommendations

- Learn RAR MTF from IW data exploiting all possible polarisations.
- Use of rapidly growing wave drifter network oven open ocean and sea ice for learning and validation.
- Use wave retrieval in sea ice for MIZ monitoring.
- Explore wave retrieval methods before azimuth SAR focusing to avoid image distortion.
- Make an open source wave-spectra-retrieval algorithm library, out of existing up to date knowledge.

Recommendations

- Multi-sensor synergies:
 - Different sensors are sensitive to different parts of the wave spectrum.
 - Better constraints at cross-overs.
 - Cross-calibration.
- Multiscale Integrated Retrievals for the Ocean (MIRO) algorithms:
 - Wind stress, wave-Doppler, currents and long-wave spectra should not be estimated separately.
 - Multiscale retrievals based on deep-learning approaches.
 - Causal filtering and/or external models should be computed.
 - Continuity constraints on the wave field (Fireworks/IW mode).
 - Possibly iterative methods.
- Future missions:
 - Benefit from MIRO algorithms.
 - Line-of-sight diversity.
 - Synoptic, high-resolution view of the air-sea interface.
