

SAR for flooding

Radar mapping of water masses is based on the difference between the backscattering mechanisms of a land surface and those of a water surface.

Calm water surface → smooth → specular backscatter (wave is directed away from the sensor) → sensor measures low values for that pixel → colour black.

Ground surface → rough → diffuse backscatter (part of wave is directed back to the sensor) → sensor measures higher values for that pixel → colour from grey to white

SAR for flooding

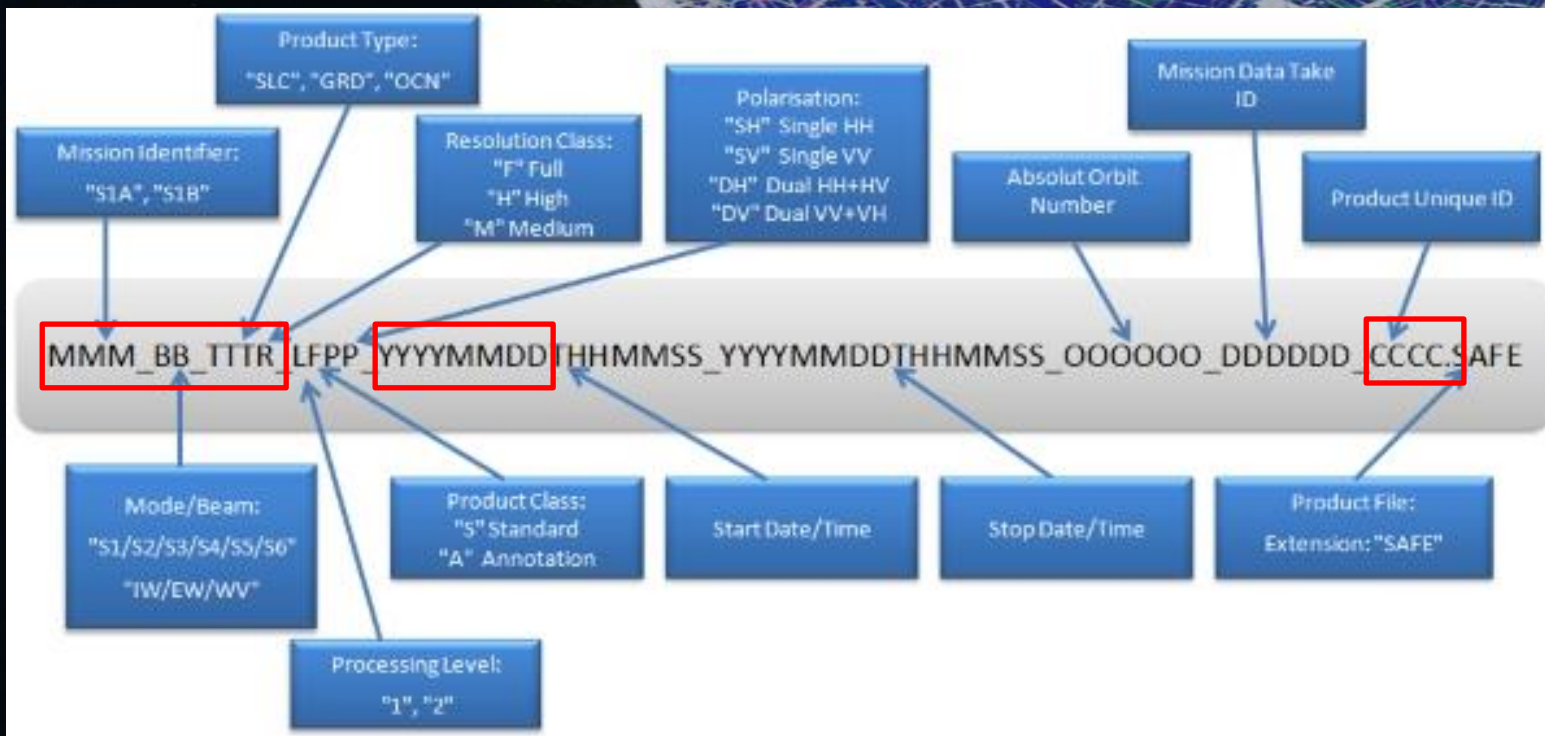

A radar image can be displayed in colour after manipulation in the SNAP toolbox. It is not always displayed in greyscale!

Create a flood zone mask

Potentially flooded pixels

Pixels potentially NOT flooded

Smooth Surface

Low backscatter = dark pixel

Rough Surface

Medium backscatter = grey pixel

Very rough surface

High backscatter = white pixel

Some questions:

Do all pixels with values below
my threshold correspond to
flooded areas? (type 1 error)

Some questions:

Do all pixels with values below my threshold correspond to flooded areas? (type 1 error)

No:

- Ground pixels with low backscatter due to noise are not removed with preprocessing.
- Smooth objects with low values (e.g. roads) will appear in the mask.

Some questions:

Will all flooded areas have
values below my threshold?
(type 2 error)

Some questions:

Will all flooded areas have
values below my threshold?
(type 2 error)

No:
backscatter in a flooded pixel may be higher
than my threshold due to noise or structures
present in the water (vegetation,
infrastructure...).
